Bibliographic note. Doctoral metallurgist.

Генеральная полиграфия и научно-техническая литература Министерства народного хозяйства СССР. Москва, изд-во АН СССР, 1959. 165 п. 3,750 экземпляров.

Ш. И. Гризита, corresponding Member, USSR Academy of Sciences; Ed. of Publishing House; V. A. Fedorov, Tech. Ed.; Yu. V. Svetlov.

This book is intended for metallurgists and welding engineers.

Contents. This is a collection of scientific papers dealing with the formation of hot cracks in ingots, castings, and welded products. Some papers are concerned mainly with the action of mechanisms of the phenomena of hot cracking in various types of structures such as heat-treating processes. Substantial evidence is given to identify some of the causes of hot cracks. Various means of preventing and preventing the phenomena are described. A number of references, both Soviet and non-Soviet, accompany the papers. Prev.-Kharkov Institute of Technology, L. D. Gerasimov and V. I. Savchenko. Formation and Prevention of Hot Cracks in Metal Castings.

As a criterion for the quantitative determination of the resistance of steel to the formation of exterior hot cracks, the author

uses the concept of "crack resistance", or

the time required to form a crack during the heating of a standard specimen with fixed load ends.

For mild carbon steel and

alloy (Cr, Mo) structural steels, pouring temperature is one of the important factors in crack development. Poured the molten

steel into a mold at the temperature of the liquidus or below should be

done as soon as possible.

A direct relationship between the crack resistance and

the mechanical properties has been established.

The character of the main measures for controlling hot cracking of steel castings by changing the composition and conditions helps to indicate the crack resistance. However,

the author does not consider the effect of resistance of steel,

of aluminum, magnesium, molybdenum, and vanadium to carbon steel or

to the formation of hot cracks.

The author recommends to pour the molten steel at a rate so as to ensure a ratio of $H/d \leq 1.5$.

Sukhorukov, E. N., I. V. Lopatin, and L. M. Postnikov. Formation of Hot Cracks in Steel Castings.

The author recommends the following measures for controlling hot

cracking in steel castings: 1) decreasing the size of the casting and eliminating projections by casting in several places with subsequent

removal of the projections; 2) regulation of the cooling rate of

various parts of the casting and elimination of coning-like parts;

3) sectionalizing the casting or their elements;

4) reduction of thickness of the casting and

eliminating fillets (radii); 5) increasing the pli-

ing walls at angles of less than 90°; 6)

strengthening weak points through the use of chills

and ribbing; 7) regulating the metal composition, so as to reduce the probability of crack

development. Considerant application of these measures, the author states,

will effectively prevent hot cracks from developing. Conscientious appli-

cation of these measures, the author states, will effectively prevent hot

cracks from developing.

TITLE:

New methods of determining casting properties of high-temperature alloys

PERIODICAL: Referativnyy zhurnal, Metallurgiya, no. 6, 1962, 80, abstract 61503
(V sb. "Novoye v liteyn. proiz-ve. No. 3", 1960, 216 - 237)

TEXT: New methods of determining the temperature of molten metal, its flowability, linear shrinkage, tendency to hot crack and film formations are described. To measure the temperature from 1,150 to 1,850°C W-Mo thermocouples and electronic automatic potentiometers are used. The temperature can be measured by a short immersion or by placing stationary thermocouples in the lining of the ladle and also by inserting a thermocouple in the riser or central tube to measure the temperature of metal flow. W-Mo thermocouples are 300 times cheaper and have a 2.5 times longer service time than Pt/Rh-Pt thermocouples. For measuring flowability a new "helical probe" method is developed. By this method a dry rod having an inside helical canal of triangular cross-section of $8 \times 7 \text{ mm}^2$ is put on

Card 1/3

New methods of determining casting...

the W-Mo thermocouple. When the thermocouple is immersed to different depths into the alloy the latter fills the helical probe to different lengths depending on its flowability, and the potentiometer records the temperature of the metal. When the spiral is taken out its length is measured by means of a graduated plexiglass cylinder. The described method broadens the temperature range of the flowability investigation from the liquidus temperature to the zero flowability temperature. To determine the linear shrinkage a sample is poured, one end of which is fixed against the flask and the other butts against an invar pin moving the free end of a thin elastic plate. Pickups connected in an electric resistance bridge are pasted on the plate. A shrinkage of the sample causes a bend of the plate which is accompanied by a change of electromotive force on the output terminals of the bridge. A preliminary graduation of the pickups is made. By means of the same device the tendency of samples to hot crack formation is determined. The tendency to film formation on the molten metal surface is determined by the pulse temperature of a radiation pyrometer directed to the surface of the metal cooling off in a crucible. A repeated overheating without deoxidation contributes to an earlier film formation. The tendency to film formation is determined by reading the temperature of molten deoxidized metal at the first cooling after remelting

the fresh charge. The higher the temperature at which a jump of the pulse of the radiation pyrometer is observed, the stronger the tendency of the metal to film formation.

TITLE: River-Runoff Regulation Over Many Years In Case of Two Cascade-Operated Hydroelectric Power Plants

PERIODICAL: Izv. vyssh. uchebn. zavedeniy. Energetika, 1958, Nr 3, pp 117-125

ABSTRACT: In order to determine the planned firm power of two hydroelectric cascade plants, formulae are developed for the probability distribution functions for filling the reservoirs and a two-dimensional function of probability distribution for simultaneous filling of both reservoirs. The probability-distribution density is connected with the unknown firm power by a simple relationship. The simplest case of constant-output regulation of both plants is considered; in this case, the probability distribution curves for filling each reservoir can be constructed independently. Bibliography: 6 items.

Grigorian, V. M. Properties of refractory works
at Chasov Yar, Semiluki, and Borovichi works
Sov. Met., 1936 [10], 16-19. The chemical composition
and physical properties of firebrick used for the con-
struction of blast furnaces should satisfy certain re-
quirements. The various physical properties of fire-
brick of the above mentioned works are studied. These
brick have the following properties: (1) The volume
of open pores for Chasov Yar brick is 5.5 to 10%, in the mean,
for Semiluki brick 11.5 to 13.5%, and for Borovichi brick
12.5 to 14.5%, in the mean. (2) The total porosity of
Chasov Yar brick is 11.5 to 19.5%, of Semiluki brick 23
to 25%, and of Borovichi brick 24.5 to 27.5%, in the mean.
(3) In respect to chemical composition, the Semiluki and
Borovichi brick Al₂O₃ content is 37 to 40%, and that of
Chasov Yar brick is 32 to 36%. The content of Fe₂O₃
in all these brick varies from 1.5 to 2.5%.

TITLE:

On the automation of horizontal distribution of burden in blast furnaces. (K avtomatizatsii gorizonta'l'nogo raspredeleniya shikhty v domennykh pechakh).

PERIODICAL:

"Stal'" (Steel), 1957, No.4, pp.300-304 (U.S.S.R.)

ABSTRACT:

The possibility of automising the operation of the burden distributor proposed by A. S. Ayukov is outlined. The above distributor (Fig.1) differs from the usual one in that it does not rotate, instead a rotating hopper with an exentric outlet is set over it (Fig.1). The proposed automation is based on impulses from a number of thermocouples placed on the periphery of the furnace throat. The electric circuit is described (Fig.2). The arrangement is such that ore charges are dropped on the zone of the hottest thermocouple and coke charge onto the coolest zone. Automation of the usual distributor is also possible, but the scheme in this case is more complicated as an automatic correction of displacement angle is required. The scheme proposed is explained. Thermocouples placed in the gas offtakes can also be used for the correction of the burden distribution. The method used in the Azovstal' Works (not automatic) is described. There are 5 diagrams, 1 tables and 2 Russian references.

TITLE: The Problem of the Motion of the Charge in the Melting Furnace (K voprosu o dvizhenii stolba shikhty v domennoy pechi)

PERIODICAL: Nauchnyye doklady vysshey shkoly. Metallurgiya, 1958,
Nr 3, pp 76 - 80 (USSR)

ABSTRACT: In melting furnaces an interaction between the shell lining and the charge takes place. It is necessary to take into consideration the friction between the charge materials and the wall. Thereby the friction coefficient as well as the work performed by the frictional forces are taken into account. The friction coefficient is: $\phi = \operatorname{tg} \psi = 0.7$. The tangent of the angle of inclination between the wall and the center-line of the shaft amounts to

Card 1/2 $\operatorname{tg} \alpha_{sh} = \frac{1.315}{16} = 0.08225$. The work of the friction forces amounts to $A_{sh} = 0.8 \text{ tm/sec}$. Figure 2 shows the

The Problem of the Motion of the Charge in the Melting Furnace SOV/163-58-3-14/49

distribution of work of the friction forces across the elements of the vertical sections of the shaft furnace. A considerable decrease of the friction forces is obtained by the increase of the angle of inclination between the wall and the center-line. In figure 3 the interdependence between the ratio of the friction forces and the volume of the furnaces is shown. The curve plotted tends to show a decrease of the friction forces where the effective volume of the furnace is raised. There are 3 figures, 1 table, and 1 reference, which is Soviet.

TITLE: The Influence of the Position of the Combustion Zone on the Operation of a Blast Furnace (Vliyanie raspolozheniya zony goreniya na rabotu domennoy pechi)

PERIODICAL: Stal', 1958, nr 6, pp 495 - 502 (USSR).

ABSTRACT: The relationship between the parameters of the combustion zone and the distribution of materials in the throat is discussed in the light of literature data (mainly Russian references are quoted) and authors' own investigations of the combustion zone of two furnaces and studies of the burden descent on the blast furnace models. During the authors' investigations at constant blowing conditions, the length of the combustion zone varied from 1 200 to 1 800 mm. This variation they think was due to the thermal state of the hearth as generally with shorter combustion zones the content of silicon in iron was higher. If the hearth becomes cooler, the heat transfer from the combustion zone increases, thus the temperature of the combustion zone decreases, the length of the combustion zone increases and the combustion process takes place in a bigger volume. This is demonstrated in Figure 1,

Card 1/8

SOV/133-58-6-4/33

The Influence of the Position of the Combustion Zone on the Operation of a Blast Furnace

where the ratio of the length of combustion zone to the distance from the tuyere nozzle to the focal point of combustion is plotted against the intensity of combustion in the focal point of the combustion zone. The latter was characterised by the concentration of CO_2 in the focal point. According to the

authors, the kinetic energy of blast can influence only the initial part of the combustion zone. This influence becomes obvious only on attaining a certain level of kinetic energy, different for different furnaces. Apparently, at low kinetic energy of the blast stream, it is pierced by lumps of coke near to the tuyere nozzle and the combustion starts in the whole volume of the stream. At a higher value of the kinetic energy of the blast stream, the lumps of coke cannot pierce the stream near the tuyere nozzle and the combustion process near the tuyere nozzle takes place only on the periphery of the stream (Figures 2 and 3). The gas permeability of the burden column also has an influence on the length of the combustion zone; the latter increases with decreasing permeability. The blast temperature has little influence on the position of the focal point of the combustion zone. On the other hand, the charging

Card 2/8

SO:/133-58-6-4/33

The Influence of the Position of the Combustion zone on the
operation of a Blast Furnace

sequence (CCOOL or OOCCL) has an influence on the position of the focal point of the combustion zone. This is explained by the influence of the velocity of the removal of combustion products which will depend on the gas permeability of the burden layer above the combustion zone. As the largest decrease in the volume of the solid phase (40-50%) in the burden column and a corresponding increase in the permeability are observed on the level of melting (in places of maximum accumulation of ore) therefore, a high gas permeability of the column is attained on the vertical of the sector of the most intensive melting of ore. The decrease in the packing density of the burden depends to a large extent on the velocity of its descent. From the work on models (Figure 4), the maximum rate of the descent of burden should take place over the focal point of the combustion zone. When the projections of the combustion zones and sectors of maximum concentration of ore are on a horizontal plane, the gas permeability of the burden over the combustion zone will be at a maximum. A comparison of diagrams of changes in the composition of gas along the tuyere axis and corresponding to them, the diagrams

Card3/8

SCV/133-58-6-4/33

The Influence of the Position of the Combustion Zone on the Operation of a Blast Furnace

of changes in the composition of gas along the throat radius indicated that there is a definite relationship between the position of the maximum CO₂ content along the throat radius and the position of the focal point of the combustion zone, namely, the two points have a tendency to coincide along a vertical line. When the position of the maximum of CO₂ content in the top gas is shifted, the focal point of the combustion zone is also shifted in the same direction. It was found that the projection of the position of maximum CO₂ along the throat radius onto a horizontal plane, passing through the tuyere axis, is situated at a definite distance from the tuyere nozzle (this was different for the two furnaces investigated). However, there are some limits within which the focal point of the combustion zone can follow the position of the maximum CO₂ content along the throat radius, that is, when the latter is near to the centre or to the wall of the throat. In these cases, the efficiency of evacuation of the combustion products ceases to be the dominating factor and the position

Card4/8

SCV/133-58-6-4/33

The Influence of the Position of the combustion Zone on the Operation of a Blast Furnace

of the focal point of the combustion zone will be subjected to the influence of other factors. Observations of the operation of furnaces indicated that when the position of maximum CO₂ content along the throat diameter and the combustion zone do not coincide vertically, the utilisation of the gas stream deteriorates (Figure 5). The influence of the parameters of the combustion zone on furnace operation was studied on a flat glass model (scale 1:25, Figure 4). The action of combustion zones was simulated by openings on the tuyere level, through which the burden material (chrome-magnesite, 2-3 mm in size) was flowing out of the model. These formed ellipsoid zones of material with a considerably lower packing density. When the distances of the outflows from the walls were small, the ellipsoid zones were intersected by the walls (Figure 6a). On shifting the outflows towards the centre, the ellipsoid zones did not intersect with walls (Figure 6b). The phenomenon is compared with the operation of furnace Nr 1 on the Nizhne-Saldinskiy Works (working volume 330 m³ and hearth diameter, 5 m). The furnace

Card 5/8

SCV/133-34-6-4/33

The Influence of the Position of the Combustion zone on the Operation of a Blast Furnace

was operating peripherally despite changes of charging sequences. Only when the tuyeres were pushed deeper into the furnace and their diameter reduced did its operation improve considerably (i.e. measures were taken to shift the combustion zone towards the centre). The size of the "dead man" also depends on the position of the combustion zones; with increasing distance between two opposite combustion zones the size of the "dead man" increases. The same results are obtained by decreasing the size of the outflow. On the other hand, by increasing the size of outflow, the intersection of the ellipsoid of low packing with walls takes place earlier and a comparatively large part of these zones appears as it was outside the furnace profile. In a blast furnace, this would increase the peripheral working. Thus, a shift of tuyeres deeper into the furnace appears to be more effective in improving the distribution of the gas stream in the furnace than an increase in the size of combustion zones. The pressure of the burden materials on the horizontal plane at tuyere level with increasing height of the burden column was also investigated on the model. The results obtained agreed

Card6/8

SOV/133-58-6-4/33

The Influence of the Position of the Combustion Zone on the Operation of a Blast Furnace

with the views on the behaviour of granular materials during their flow (Ref 19). On the basis of the results obtained the following conclusions are drawn: 1) the position of the focal point of the combustion zone of a normally operating furnace depends not only on the temperature and volume of the blast but also on the position of zones of the most intensive formation of molten masses; 2) The distribution of burden materials in the furnace throat should be related to the position of the combustion zones; 3) A rational protrusion of tuyeres helps in containing the ellipsoid zones into the furnace profile; 4) The influence of the bosh on the descent of materials is insignificant and with a correct co-ordination of the furnace profile with the ellipsoid zones - completely absent; 5) The optimum position of the maximum CO_2 content along the throat diameter in relation to the position of combustion zones should be experimentally determined for each furnace.

TITLE: Correlations Between the Structure of the Charge Column and the
Gas Flow in Blast Furnaces

PERIODICAL: Tr. Ural'skogo politekhn. in-ta, 1958, Vol 73, pp 123 - 159

ABSTRACT: The author points out that many existing notions on factors deter-
mining the motion of materials in blast furnaces need to be re-
considered. The author stresses the important part of the smelting
process as one of those factors. It is suggested to consider the
motion of materials into combustion seats by analogy with the theory
developed by G.M. Malakhov on the outlet of ores from the bin through
hatches. The author notes the overestimation of the loosening
effect of inclined shaft walls and of the deviation from the verti-
cal of the charge motion. It is shown by calculations and ob-
servations on a model that small and large lumps of the material
under the effect of a strong gas flow are deflected towards the

Card 1/2

SOV/137-59-5-9794

Correlation Between the Structure of the Charge Column and the Gas Flow in
Blast Furnaces

furnace walls if they are poured from a large cone. The character of the material distribution on the throat depends mainly on the rate of the gas flow. It is pointed out that if the charged materials roll down along the charge slope, a considerable portion of particles must be displaced upwards. The blast furnace operation is controlled by changes in the ratio of ore charge component to the coke component. It is recommended to increase the weight (of one cubic meter) of the ore and sinter and to reduce the ratio of the ore component to the coke one. The distribution in the horizontal direction was investigated and the deficiency of the McKee distributor was detected. It is recommended to use eight rotating stations instead of six. Experiments on a blast furnace model showed the absence of mass displacements of the particles in the horizontal plane when homogeneous materials were poured from a large cone into the blast furnace. Data are presented on the efficiency of gas flow control in a series of blast furnaces. Steady operation of the blast furnace is one of the basic conditions to obtain high efficiency of the gas flow control by changes in the charge. Efficiency of the charge control can be considerably raised by automated composition of the charge.

TITLE: The Application of Tensometry in an Apparatus for Investigating the Kinetics of Reactions (Ispol'zovaniye tenzometrii v apparature dlya issledovaniya kinetiki reaktsiy)

PERIODICAL: Nauchnyye doklady vysshey shkoly. Metallurgiya, 1959, Nr 2, pp 250 - 251 (USSR)

ABSTRACT: The method developed in the institute mentioned under "Association" is based on the measurement of the elastic deformation of a steel ruler by tensometer feelers. The apparatus is shown in figure 1. The steel ruler is clamped fast at one end, the sample to be investigated is hung to the other end. The bending of the ruler by the weight of the sample is measured by means of the resistance change of 4 (2 upper and 2 lower) tensometer feelers. The scheme of the measuring bridge circuit according to the zero method is shown in figure 2. The authors see the advantage of this apparatus in the fact that - in contrast to balances - the sample remains hanging during the reaction to be investigated, making possible a continuous measurement of weight changes. The apparatus originally built for the investigation of reduction processes can also be applied to other

Gruzinov, Vladimir Konstantinovich

Upravleniye gazovym potokom v domennoy pechi programmnoy zagruskoy (Gas-Transit Control in Blast Furnaces by Programmed Charging) Sverdlovsk, Metallurgizdat, Sverdlovskoye otd-niye, 1960. 214 p. Errata slip inserted. 3,150 copies printed.

Reviewer: V.G. Manchinskiy; Ed.: S.I. Sharov; Ed. of Publishing House: M.M. Syrchnina; Tech. Ed.: R.M. Matlyuk.

PURPOSE: This book is intended for engineers working in blast-furnace operations and in scientific research institutes; it may be useful to students of metallurgy at schools of higher technical education.

COVERAGE: The book deals with theoretical principles of gas-transit control in blast furnaces. The author discusses the stock composition in the shaft, analyzes changes in its structure occurring under the influence of various factors, and describes the physical characteristics of stock passage. Also

Card 1/6

Gas-Transit Control (Cont.)

SOW/4684

discussed are methods and techniques of gas-transit control in operation at the larger blast furnaces. Prospects for the development of gas-transit control by means of programmed distribution of raw materials are considered. The author thanks Docent V.G. Manchinskiy, Candidate of Technical Sciences, who reviewed the manuscript, Professor S.I. Sharov, Doctor of Technical Sciences, who edited the book, and Profs. A.I. Ramm and A.N. Pokhvisnev, Doctors of Technical Sciences, for their observations regarding the book. There are 151 references: 132 Soviet, 15 English and 4 German.

AUTHORS: Grekov, P.N., Gruzinov, V.K., Lazarev, B.L.
TITLE: Rational Arrangement of Transmitters for Automatic Control of the Horizontal Distribution of the Charge
PERIODICAL: Stal', 1960, No. 11, pp 977-980

TEXT: The accuracy and the quick reaction of the automatic control system of the revolving distribution of the charge primarily depends on the sensitivity, the accuracy and the long useful life of nickel-cobalt and "alumel" (an alloy containing Ni, Al, Mn, Si and Co) thermocouples which are usually arranged on the upper level of the furnace brickwork under the armor plates. For several reasons, however, this arrangement does not insure sufficient sensitivity of the thermocouples, which are placed in thick-walled protective tubes, arranged 2-2.5 m below the level of the charge; the changes in the distribution of the materials in the charge are, therefore, indicated only with a considerable delay. The thermocouples, consequently, record only very considerable fluctuations in the distribution of materials and of the gas flow on the periphery of the furnace. Moreover, the useful life of these thermocouples does not exceed 5-6 months, mainly on account of the sooty carbon

Card 1/3

S/133/60/000/011/003/023
A054/A029

Rational Arrangement of Transmitters for Automatic Control of the Horizontal Distribution of the Charge

deposits in the protective tubes which compress the casing of the thermocouples, thus deforming them and damaging the insulation of the thermoelectrodes. Tests were carried out to eliminate these drawbacks by arranging a large number of thermocouples (6,8,12 and more) in the vault of the blast furnace above the armor plates. By analyzing the factors influencing the operation of thermocouples placed above the charge level, it was found that the operation of the revolving distributor greatly affects the change of readings of the conditions on the furnace periphery only if the materials fed into the furnace are distributed evenly. However, the diagrams representing the readings of these thermocouples are not suitable to locate gaps in the charge. In order to facilitate the location of gaps, the thermocouples arranged according to the new system are connected into batteries; moreover, a change-over switch was included in the system. The gap in the charge can very easily be located on the periphery of the furnace by one of the two positions of this change-over switch, in which the electromotive force of the thermocouples connected in the battery is zero. This new arrangement of the thermocouples greatly improves the sensitivity, accuracy and reliability of the control system of the revolving distri-

TITLE: On the calculation of corrections for depth based on the deviation of actual from calculated speed during echosounding

CITED SOURCE: Tr. Morsk. gidrofiz. in-ta. AN USSR, v. 28, 1963, 92-98

TOPIC TAGS: echosounding, fathometer readings, speed of sound, fathometer correction, Del Grossi, Matthew tables, sound in water, hydrological stations, Mikhail Lomonosov, Zubov tables

TRANSLATION: The variation of correction for depth on the speed of sound depending on the sources used for the calculations is investigated. For calculations the speed of sound is taken as 1500 m/sec, the standard for all modern Soviet fathometers. The calculations made were for 11 deepwater hydrological stations made during the second voyage of the expeditionary ship Mikhail Lomonosov in March-April 1958 and for 11 repeated stations made at the same points by the same ship in October-November 1958. A comparison of the results established how much the results
